Kopros[®] H should be applied every 30 days.

In order to maintain a clean bedding, it is advisable to pick up the biggest manure quantities on a daily basis.

In addition to picking up manure, it is essential to scrape off those areas of the bedding that are excessively soaked with urine which can no longer be absorbed.

To replace the removed bedding parts, it is recommended to add a new layer of the same material (straw or other), to maintain a bedding thickness of between 15 and 20 centimetres.

Kopros[®] H is ideal for helping to form or maintain a thick, soft and stable bedding for your horse, e.g. straw pellets, wood shavings or compost bedding. Once applied, the micro-organisms start a process of decomposition of organic matter by digesting dung and urine and continue their actions over the following weeks. The application should be repeated every month to ensure continuous development.

However, if your stable is made up of traditional straw bedding which is changed frequently, you and your horse will not benefit fully from the properties of Kopros[®] H. In this case, we advise you to apply it directly to the manure pile to accelerate the composting process and reduce odour nuisance.
